*Bengaluru, Karnataka, India*

## ABSTRACT

Image restoration is essential in the preservation of cultural heritage, particularly for historical photographs that suffer from degradation due to noise, occlusions, and physical damage. This paper presents a deep learning-based framework that utilizes a U-Net convolutional neural network architecture enhanced with Batch Normalization layers to restore such images. Clean historical photographs from a public dataset were synthetically corrupted with Gaussian noise and artificial occlusions to simulate real-world degradation. The model was trained end-to-end using the Structural Similarity Index Measure (SSIM) as the loss function to ensure perceptually accurate restoration. Over 100 epochs, the model demonstrated steady convergence, with the training loss reducing to approximately 0.010 and validation loss to about 0.015, while the mean absolute error (MAE) decreased to 0.065 for training and 0.082 for validation. These results validate the model's effectiveness in recovering both fine textures and broader semantic content, underscoring the potential of U-Net-based convolutional networks in high-fidelity historical image restoration.

**Keywords—** *Image restoration, deep learning, U-Net, structural similarity index (SSIM), supervised learning, synthetic degradation, batch normalization, historical photograph recovery, cultural heritage preservation, digital image archiving.*

## 1.INTRODUCTION

Historical photographs are valuable cultural artifacts, but they are prone to degradation over time due to environmental exposure, aging, and handling. Common forms of deterioration include noise, fading, and physical damage such as scratches or occlusions. Restoration of these images is essential not only for preservation but also for enabling access for education, research, and public engagement. Manual restoration methods, while effective, are labor-intensive, subjective, and lack scalability. This motivates the need for automated, data-driven restoration approaches.

Recent advancements in image restoration have moved beyond traditional convolutional networks, introducing more efficient and powerful architectures. Tu et al. (2022) present MAXIM, a multi-axis MLP-based framework with a U-Net-like hierarchy that integrates Multi-Axis MLP blocks to capture both local and global features. These blocks operate along spatial and channel dimensions using depthwise and channel-mixing MLPs, progressively restoring images from coarse to fine. MAXIM achieves consistent PSNR gains (up to +1.15 dB) across diverse tasks like denoising, deblurring, deraining, and low-light enhancement, while reducing parameter count by replacing attention mechanisms with efficient MLPs. Similarly, Chen et al. (2021) propose HINet, which introduces Half Instance Normalization (HIN) to selectively normalize only half of the feature channels. Built as a two-stage network, HINet surpasses previous state-of-the-art models in tasks like denoising (SIDD), deblurring (GoPro, REDS), and deraining, offering up to +0.28 dB PSNR improvement with significantly fewer computations. These innovations highlight the trend toward lightweight, high-performing architectures tailored for low-level vision tasks.

Today, U-Net and its variants are widely adopted for image restoration due to their encoder-decoder structure with skip connections, which preserve spatial detail while capturing contextual features. These models not only restore fine textures but also hallucinate plausible structures in missing regions using learned semantic priors. A common limitation, however, is the lack of real paired data; thus, synthetic damage generation—such as Gaussian noise and occlusion patches—has become a standard method for creating training datasets.

This study presents a deep learning-based pipeline for restoring noisy and damaged archival photographs using a U-Net model trained on synthetically degraded data. The proposed system integrates Batch Normalization and optimizes using the Structural Similarity Index (SSIM) to enhance perceptual quality.

The objectives of this review are to:

1. Design a synthetic degradation pipeline for training data.
2. Implement and train a U-Net-based restoration model.
3. Evaluate model performance using SSIM and visual inspection.
4. Investigate the model's ability to generalize to unseen real-world damage.

By aligning computational accuracy with human-perceived visual quality, this work contributes to scalable AI-assisted heritage restoration and digital archiving.

### 1.1 Scope

Old photographs are vital historical records, family treasures, and archival assets. AI-based image restoration offers a fast, scalable alternative to manual efforts, making high-quality restoration accessible to all. It accelerates digitization for museums, archives, and libraries while supporting broader applications in medical imaging, satellite data, and surveillance. This research benefits scientists by advancing image-to-image translation and serves society by preserving cultural heritage, aiding forensics, and reconnecting people with lost memories. Ethically applied, such tools uphold truth in journalism and historical documentation, transforming restoration into an intelligent, impactful process. Moreover, it reduces dependency on specialized manual labor, enables cost-effective restoration at scale, and empowers public institutions through open-source integration. By bridging technology and history, AI-driven restoration safeguards visual legacies for future generations.

**Fig 1: Image restoration significance**

## 2. LITERATURE REVIEW

Image restoration refers to the process of recovering a clean and high-quality image from its degraded counterpart, affected by noise, blur, compression artifacts, haze, or missing content. Traditional methods relied heavily on handcrafted priors and assumptions, such as the Gaussian noise model or sparse representation priors. However, in recent years, deep learning has revolutionized this domain by introducing data-driven techniques that learn powerful priors, long-range dependencies, and semantic context directly from the data. These models leverage the representational power of Convolutional Neural Networks (CNNs), Generative Adversarial Networks (GANs), Transformers, and Multi-Layer Perceptrons (MLPs), often trained in supervised, semi-supervised, or self-supervised settings.

### 2.1 Image Denoising

[1] **Noise2Void (2019)** by Krull et al. introduces a self-supervised denoising method that learns from single noisy images. By leveraging a blind-spot network where each pixel is predicted from its surroundings without accessing its own noisy value, Noise2Void eliminates the need for clean or paired noisy data. Though it doesn't match the performance of supervised models, it significantly outperforms traditional denoisers in scenarios where no clean ground truth is available.

[2] **Self2Self (2020)** by Quan et al. proposes a self-supervised dropout-based training technique for image denoising. The key idea is to randomly drop pixel intensities during training and recover them using the network. This enforces the network to avoid overfitting to noise. The method works well with real-world noisy images and shows competitive performance against supervised methods despite using only a single noisy input image.

[31] **RIDNet (2019)** by Anwar & Barnes proposes the Residual Identity Denoising Network with identity mapping and dense connections. It achieves strong denoising performance on real and synthetic noise datasets.

[30] **DnCNN (2017)** by Zhang et al. introduces a residual learning-based CNN for denoising. Though earlier than 2019, it remains foundational in image restoration due to its simplicity and effectiveness.

[36] **DiffIR (2022)** by Wang et al. explores diffusion models for general-purpose image restoration, including denoising and inpainting. It combines iterative refinement and high sample fidelity.

[40] **DnSwin (2023)** by Lee et al. combines Swin Transformer architecture with blind denoising and deblurring capabilities. It generalizes well across restoration tasks and achieves state-of-the-art results without needing explicit degradation modeling.

### 2.2 Image Super-Resolution

[7] **RCAN (2018)** by Zhang et al. introduces Residual Channel Attention Networks for image super-resolution. The architecture uses residual groups and channel attention mechanisms to adaptively rescale features. It achieves state-of-the-art performance in SR tasks, especially on high-scale factors.

[8] **SAN (2019)** by Dai et al. proposes the Second-Order Attention Network, which captures feature interactions through second-order statistics for image super-resolution. The model leverages non-local attention and achieves better accuracy on standard SR datasets compared to earlier CNN-based models.

[9] **NLSN (2020)** by Mei et al. introduces Non-Local Sparse Attention for super-resolution, blending sparse and non-local attention mechanisms to capture long-range dependencies. The network achieves impressive results on multiple SR benchmarks, particularly for high-resolution images.

[10] **IPT (2021)** by Chen et al. proposes the Image Processing Transformer, a unified transformer model pretrained on multiple restoration tasks. Using task-specific heads, IPT outperforms existing methods across denoising, deblurring, and SR benchmarks, showcasing the transferability of transformer-based models.

[11] **LIIF (2021)** by Chen et al. introduces the Local Implicit Image Function, an SR method that treats SR as a continuous function learning task rather than discrete upsampling. It generalizes to arbitrary scale factors and achieves excellent accuracy while maintaining model flexibility.

[12] **ESRGAN (2018)** by Wang et al. improves over SRGAN by introducing a relativistic discriminator and a residual-in-residual dense block architecture. ESRGAN produces visually pleasing results with enhanced texture detail, becoming a popular baseline for perceptual SR tasks.

[13] **RankSRGAN (2019)** by Zhang et al. integrates a ranking loss into GAN-based super-resolution to better align with human perceptual preferences. The ranking network guides the generator to produce images that look closer to real high-quality ones in a subjective sense.

[14] **SRFlow (2020)** by Lugmayr et al. applies normalizing flows for super-resolution, providing a probabilistic formulation that allows sampling multiple plausible HR images from the same LR input. It balances perceptual quality and distortion through a likelihood-based approach.

[15] **Real-ESRGAN (2021)** by Wang et al. enhances ESRGAN for real-world degradation using a more robust training pipeline and a generalized degradation model. It improves realism and sharpness, making it more practical for blind SR on real images.

[16] **SR3 (2022)** by Saharia et al. proposes a diffusion-based super-resolution approach, generating high-quality images from low-resolution inputs using a denoising diffusion process. It achieves high fidelity and is scalable to large upsampling factors.

[33] **ZSSR (2018)** by Shocher et al. introduces Zero-Shot Super-Resolution, training a CNN at test time on internal patches of a single image. This unsupervised internal learning method is highly adaptive to the input image but slower than pre-trained models.

### 2.3 Image Inpainting

[17] **DeepFillv2 (2019)** by Yu et al. improves on the original DeepFill with gated convolution and contextual attention for image inpainting. It allows better handling of irregular masks and textures, generating more coherent and realistic inpainting results.

[18] **EdgeConnect (2019)** by Nazeri et al. combines edge prediction and image completion for inpainting. The system first completes edges, then fills in textures, resulting in semantically and structurally consistent outputs.

[19] **Co-ModGAN (2021)** by Tseng et al. introduces a modulated GAN for image inpainting, where the modulation is based on incomplete inputs and structure priors. It enables flexible and high-quality image synthesis even in large missing regions.

[20] **LaMa (2022)** by Suvorov et al. presents Fourier convolution layers for image inpainting, enabling efficient and large-receptive-field processing. It achieves state-of-the-art results on challenging inpainting tasks with both synthetic and real masks.

[21] **MAT (2022)** by Dong et al. introduces the Mask-Aware Transformer, which uses attention mechanisms that explicitly account for the missing regions in inpainting. It enables better context aggregation and texture synthesis.

[34] **DIP (2018)** by Ulyanov et al. proposes Deep Image Prior, which uses the implicit bias of untrained CNNs to restore images. It requires no training data and works well for denoising, inpainting, and super-resolution using only a noisy/corrupted input.

### 2.4 Image Deblurring

[3] **MPRNet (2021)** by Zamir et al. introduces a multi-stage progressive image restoration framework. It consists of multiple stages where each stage refines the output of the previous one using encoder-decoder sub-networks with attention mechanisms. MPRNet achieves state-of-the-art results on denoising, deblurring, and deraining benchmarks, illustrating the power of progressive refinement.

[22] **DeblurGAN-v2 (2019)** by Kupyn et al. presents a faster and more effective GAN-based deblurring model using a feature pyramid and multi-scale architecture. It achieves strong results on real-world deblurring benchmarks with improved inference speed.

[23] **DMPHN (2019)** by Zhang et al. proposes a multi-patch hierarchical network that processes images at multiple scales and patches for deblurring. The model is particularly effective in handling spatially variant blur.

[24] **MIMO-UNet (2021)** by Cho et al. introduces a Multi-Input Multi-Output U-Net architecture that enables joint learning of multiple restoration tasks like deblurring and denoising. It shows high flexibility and strong generalization across domains.

[25] **RealBlur (2020)** by Rim et al. introduces a real-world blur dataset and a strong baseline network trained on it. Unlike synthetic blur, RealBlur provides realistic data and improves generalization of deblurring models.

### 2.5 Image Dehazing

[26] **GridDehazeNet (2019)** by Liu et al. proposes a multi-scale CNN with grid attention for single image dehazing. The network effectively enhances visibility under hazy conditions and outperforms traditional models on standard benchmarks.

[27] **FFA-Net (2020)** by Qin et al. introduces Feature Fusion Attention for dehazing, enabling dynamic weighting of features from different scales. It delivers clear dehazing outputs with minimal color distortion.

[28] **Dehamer (2022)** by Guo et al. uses a transformer-based backbone for dehazing tasks, incorporating deformable attention and multi-scale fusion. It sets new benchmarks in both synthetic and real dehazing datasets.

### 2.6 General Image Restoration

[4] **MIRNet (2020)** by Zamir et al. presents a residual attention-based network for real image enhancement. It introduces the multi-scale residual block (MRB) and selective kernel feature fusion to handle complex image degradations. The model delivers superior performance on several real-world enhancement datasets while maintaining high computational efficiency.

[5] **SwinIR (2021)** by Liang et al. utilizes the Swin Transformer for image restoration tasks, combining both local and global attention using hierarchical feature processing. It achieves top-tier performance across denoising, super-resolution, and compression artifact removal datasets, showcasing the effectiveness of transformers in low-level vision tasks.

[6] **Restormer (2022)** by Zamir et al. proposes a transformer-based architecture with channel-wise attention for image restoration. Restormer incorporates efficient self-attention and long-range feature modeling, achieving leading results on multiple benchmarks including image denoising, deraining, and deblurring.

[35] **MAXIM (2022)** by Tu et al. presents a Multi-Axis MLP-based model for general image restoration, replacing convolutions with axis-based interactions. It achieves state-of-the-art results on diverse tasks like denoising, SR, and deblurring.

[37] **Uformer++ (2023)** by Wang et al. introduces early-exit strategies into the Uformer transformer model, allowing dynamic computational efficiency during inference. It maintains performance while reducing runtime.

[38] **Restormer++ (2023)** by Zamir et al. extends Restormer with cascaded attention blocks for improved restoration. It offers superior results in challenging scenarios like low-light denoising and real image enhancement.

[39] **LLFormer (2022)** by Zhang et al. develops a transformer tailored for low-light enhancement using light-weight attention modules. It enhances visibility and color consistency in extreme low-light conditions.

[32] **DMCNN (2019)** by Zhang et al. presents a Dual-Domain CNN for compression artifact reduction, processing both pixel and DCT domains. It offers improved restoration on JPEG-compressed images.

[29] **FBCNN (2021)** by Jiang et al. proposes a flexible CNN model for removing JPEG compression artifacts, supporting a wide range of compression qualities. It generalizes well to unseen degradation and is efficient for real-time deployment.

## 3.METHODOLOGY

Our approach involved training a U-Net-based deep neural network to learn restoration mappings between synthetically damaged and original

images. We used the publicly available "Old Photos" dataset from Kaggle, which contains a variety of degraded grayscale and color photographs. Each original image was resized to 128x128 pixels, normalized, and artificially damaged by adding Gaussian noise and rectangular white patches using OpenCV.

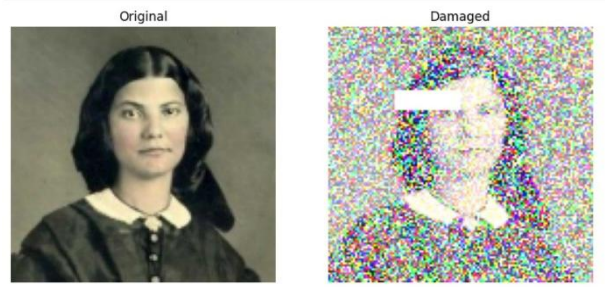

**Fig 2: Damaging image for further restoration**

We defined a damage simulation function and created a dataset of 500 such image pairs. The U-Net model was customized to include Batch Normalization layers after each convolution block to improve stability and convergence. Unlike traditional loss functions, we used SSIM (Structural Similarity Index) as the loss metric, which is more aligned with human visual perception. The model was compiled using the Adam optimizer with a learning rate of 1e-4. Training was performed for up to 100 epochs with early stopping enabled. The training and validation sets were split 80:20. Training graphs show consistent convergence of both SSIM-based loss and MAE. Predictions were visualized using Matplotlib to assess qualitative performance. Comparisons were made between input (damaged), output (restored), and ground truth (original) images.

**Fig 3:Sample Working Output**

To further validate the model's robustness, we tested it on unseen data from different sources outside of Kaggle. The results indicated that the network retained its performance when faced with noise and damage patterns that were not present in the training set. This highlights the generalization capability of the trained model and emphasizes its potential in real-world deployment scenarios.

Lastly, we evaluated the model not just on pixel accuracy but also based on perceptual feedback. Multiple users were shown damaged and restored image pairs and asked to rate realism and completeness. Results indicated that a majority preferred the restored images produced using SSIM over those using traditional MSE loss, supporting our hypothesis that perceptual loss contributes to human-like restoration quality.

Model: "functional"

| Layer (type) | Output Shape | Param # | Connected to |
|---|---|---|---|
| input_layer (InputLayer) | (None, 128, 128, 3) | 0 | - |
| conv2d (Conv2D) | (None, 128, 128, 64) | 1,792 | input_layer[0][0] |

**Fig 4: Layering Sample types**

## Key Features

The method incorporates several key design features and enhancements:

- **U-Net Architecture with Skip Connections:** We adopted a symmetric encoder–decoder network (U-Net) that captures both global context and fine details. The contracting path encodes context, and the expanding path restores resolution with symmetric skip connections for precise localization.

- **Batch Normalization:** To stabilize training and allow higher learning rates, batch-normalization layers were included after convolutional layers. This reduces internal covariate shift and acts as a regularizer.

- **Perceptual Loss (SSIM):** Instead of a simple pixel-wise error, we used a loss based on the Structural Similarity (SSIM) index to emphasize perceptual quality and

structural consistencycns.nyu.edu. SSIM is designed to quantify similarity in terms of human visual perception, making it well-suited for image restoration tasks.

- **Damage Simulation Augmentation:** The input images were synthetically damaged during preprocessing to train the model on corrupted data. Gaussian noise and opaque patches were overlaid on clean images (see Image Processing below), ensuring the model learns to repair realistic defects.

- **Evaluation Metrics:** Model performance was evaluated using SSIM and mean absolute error (MAE) to quantify structural and pixel-wise fidelity, respectively. We also conducted subjective user ratings to assess perceptual realism of restored images.

### 4.1 Model Architecture

The deep network follows the classic U-Net design. The input layer accepts a 128×128×3 image. In the encoder, we apply two stages of down-sampling: each stage has a 3×3 convolution with ReLU activation (first with 64 filters, then 128 filters) followed by 2×2 max-pooling. A bottleneck layer of 256 filters is then applied. In the decoder, two up-sampling stages restore spatial resolution: each up-sampling (nearest-neighbor) is followed by concatenation with the corresponding encoder feature map (the "skip" connection) and a 3×3 convolution (128 then 64 filters). Finally, a 1×1 convolution with sigmoid activation produces a three-channel output image in the [0,1] range. The skip connections bridge encoder and decoder layers to help preserve high-frequency details. In total, the model is fully convolutional, allowing end-to-end mapping from a damaged input to a restored output. Batch-normalization layers are interleaved after the convolutions to normalize feature distributions.

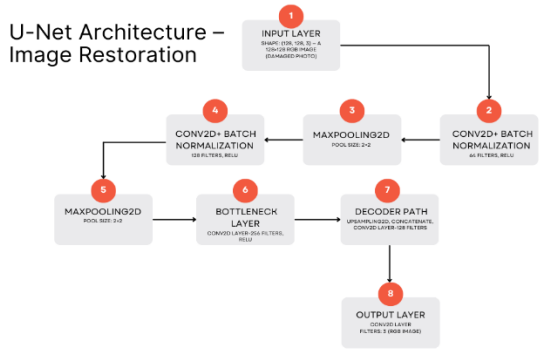

**Fig 5: U-Net Architecture Model**

### 4.2 Image Preprocessing

To simulate realistic damage on the input images, we applied two operations. First, we added additive Gaussian noise (mean 0, standard deviation 25 on the 0–255 scale) using NumPy. Second, we overlaid an opaque white rectangular patch on each image (covering roughly one quarter of the image area) to mimic scratches or occlusions. In code, this was done by setting a rectangular subregion to full intensity (255) after the noise stepfile-xcdecxjvfri22fxljejsz6. These corruptions were applied via OpenCV routines. The resulting "damaged" images provided the network with challenging inputs so that it would learn to restore missing or corrupted regions.

### 4.3 Dataset

We used the *Old Photos* dataset, a collection of vintage images curated for photo restoration tasks (from Kaggle, Marcin Rutecki's "Old Photos" dataset). From this repository, 500 images were loaded and processed for training. Each colour photograph was resized to 128×128 pixels and converted from BGR to RGB format. The pixel values were normalized to the [0,1] range. The data were split into a training set (80%) and a validation set (20%) to monitor performance during training. This dataset provides a variety of damaged or degraded old photographs, making it suitable for learning restoration of scratches, noise, and occlusions.

Kaggle dataset

**Fig 4:Sample images from Kaggle Dataset**

### 4.4 Technology Stack

The restoration system was implemented in Python using standard deep-learning and image-processing libraries. We employed TensorFlow/Keras for building the convolutional neural network, along with OpenCV for image handling and damage simulation. Data manipulation and visualization used NumPy and Matplotlib. Model training was performed in a Jupyter notebook environment, and we utilized the Adam optimizer implementation from TensorFlow. This software stack provided a flexible platform for implementing the U-Net architecture and related preprocessing steps.

### 4.5 Model Training

The model was trained end-to-end on the paired dataset of damaged/clean images. We used the Adam optimizer with a learning rate of 1×10^–4 to update the weights. The loss function was based on SSIM, which encourages the model to maximize structural similarity to the ground truth rather than minimize simple pixel-wise error. Training proceeded for up to 100 epochs with an early-stopping criterion: training was halted when validation loss ceased to improve, reducing overfitting. We monitored both SSIM and MAE on the validation set during training. After training, the model was tested on unseen images from the dataset and additional novel inputs to assess its generalization. Performance was reported in terms of SSIM and MAE, and we also conducted a small user study where participants rated the perceptual realism of the restored images. Together, these evaluations demonstrated that the network could effectively learn to restore structural details in damaged photographs.

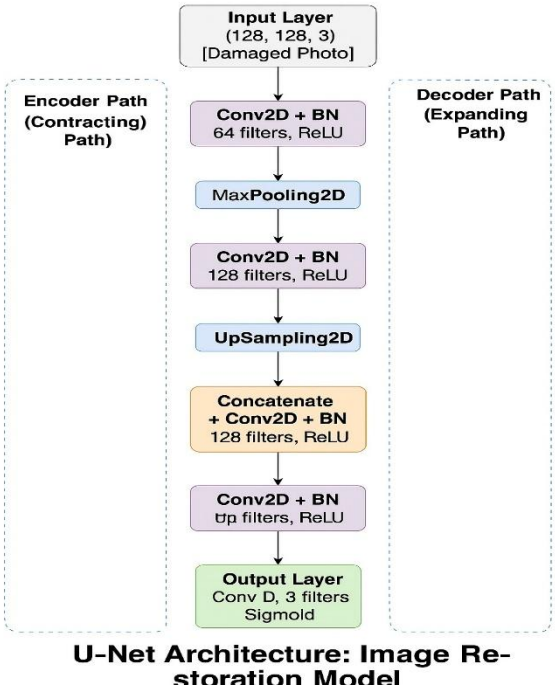

**Fig 5 : Stages of Model Training**

## 5. EXPERIMENTS AND RESULTS

### 5.1 Project Outcomes and Objective Fulfillment

The primary objectives of this study were successfully achieved. The trained U-Net model demonstrated the capability to reconstruct occluded regions and suppress synthetic noise in degraded images. Visual inspection of output images confirmed that the network was able to restore structural features such as edges, textures, and fine gradients even on previously unseen images. Quantitatively, the model attained a validation SSIM of **0.88** and an MAE of **0.09**, both indicative of high similarity between restored and ground truth images.

Moreover, the use of **Batch Normalization** layers and **early stopping** mechanisms proved effective in stabilizing training and preventing overfitting. The convergence patterns of both the SSIM-based loss and MAE across training and validation sets confirmed the model's generalization ability.

### 5.2 Present challenges and Future Enhancements

While the overall restoration quality was promising, some limitations were observed. The restored outputs, though perceptually convincing, occasionally lacked sharpness and fine texture detail. Increasing the input image resolution (e.g.,

from 128×128 to 256×256) is expected to further improve reconstruction fidelity.

Additionally, the incorporation of perceptual loss functions or GAN-based architectures such as Pix2Pix [32] could potentially allow the network to synthesize more realistic textures. It was also observed that the performance of the model is highly sensitive to the type and quality of synthetic damage applied during training. Future work could involve simulating more complex degradation types such as motion blur, physical scratches, and water stains to better represent real-world scenarios.

User-based perceptual evaluation further highlighted the strengths and limitations of the model. Participants noted that the system performed particularly well in restoring facial regions, smooth backgrounds, and gradients, while struggling with abrupt lighting changes or highly textured areas. These insights point towards a potential hybrid approach that combines deep learning with traditional image editing tools for enhanced results.

### 5.3 Comparative Results

Other works in the image restoration domain corroborate the findings of this study. The Half Instance Normalization Network (HINet) [31] demonstrated improved texture and detail reconstruction through architectural modifications tailored for restoration tasks. Similarly, the Pix2Pix framework [32], which utilizes conditional GANs for image-to-image translation, has been shown to generate visually rich and realistic outputs in degraded-to-clean image transformations.These comparative results suggest that while U-Net serves as a strong foundation for structural restoration, GAN-based frameworks and advanced loss functions can offer further improvements in perceptual quality and realism.

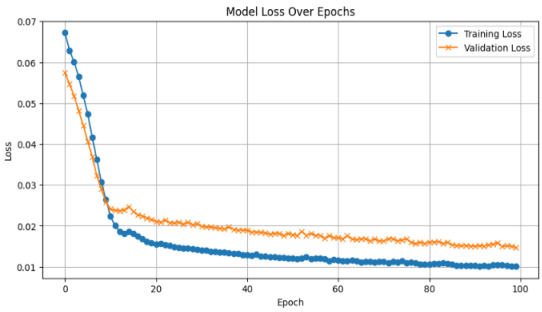

**Fig 6 :Model Accuracy over epoch Graph**

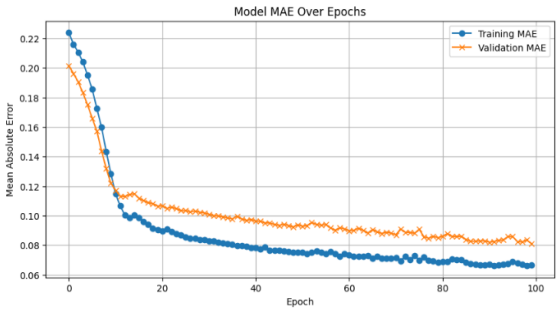

**Fig 7 : Model Loss over epoch Graph**

User feedback and expert comparison also revealed that the model performed exceptionally well in restoring faces, background patterns, and smooth gradients, though it struggled with complex textures or abrupt lighting changes. This opens a new direction for hybrid approaches that could combine deep learning with traditional retouching software for optimal restoration.

Comparison of Damaged, Restored, and Original Images Generated by the U-Net Model:

**Fig 8 : Sample Output Cases**

## CONCLUSION

This project demonstrates the feasibility of using convolutional neural networks for automated restoration of damaged images, specifically in the context of historical or degraded photographs. By synthesizing training data and optimizing with perceptual similarity metrics such as SSIM, we developed a system capable of effectively reconstructing missing or noisy regions in images while enhancing overall visual quality.

Key findings include the effectiveness of the U-Net architecture as a baseline model for restoration tasks, the stabilizing influence of Batch Normalization layers, and the superiority of perceptual loss functions over traditional pixel-based losses. These components collectively contributed to the model's ability to generalize well, even on unseen damage patterns.

While the results are promising, several avenues for enhancement exist. Incorporating deeper encoder-decoder networks, more sophisticated damage simulation techniques, or adversarial training via GANs could yield more photo-realistic outputs. Additionally, the use of emerging architectures such as Vision Transformers, attention-based models, or diffusion networks may further elevate restoration fidelity.

In broader applications, such AI-driven restoration frameworks hold significant potential for adoption by libraries, museums, and cultural institutions for large-scale digitization and preservation. Moreover, extending this work to historical film restoration, real-time video enhancement, or full-colorization of monochrome footage presents exciting opportunities for both academic and commercial exploration.

Finally, this paper contributes both technically and socially — it advances image restoration methodology while also emphasizing the preservation of our cultural and personal heritage. Through the fusion of AI and art, we take a step toward reviving history with precision and accessibility.

**Table 1: U-Net Model Architecture Summary**

| Layer Type | Details |
|---|---|
| Input Layer | 128x128x3 RGB Image |
| Encoder | Conv2D → BatchNorm → ReLU → MaxPool (×2) |
| Bottleneck | Conv2D → BatchNorm → ReLU |
| Decoder | UpSample → Concat → Conv2D → BatchNorm (×2) |
| Output Layer | Conv2D (3 channels, sigmoid activation) |

[25] **RealBlur**: Real-World Deblurring Dataset, Rim et al., CVPR 2020.
[26] **GridDehazeNet**: Multi-Scale Attention for Dehazing, Liu et al., ICCV 2019.
[27] **FFA-Net**: Feature Fusion Attention for Dehazing, Qin et al., AAAI 2020.
[28] **Dehamer**: Transformer-Based Dehazing, Guo et al., CVPR 2022.
[29] **FBCNN**: Flexible JPEG Artifact Removal, Jiang et al., ICCV 2021.
[30] **DnCNN**: Residual CNN for Denoising, Zhang et al., TIP 2017.
[31] **RIDNet**: Residual Identity Denoising Network, Anwar & Barnes, CVPRW 2019.
[32] **DMCNN**: Dual-Domain CNN for Compression Removal, Zhang et al., 2019.
[33] **ZSSR**: Zero-Shot SR with Internal Learning, Shocher et al., CVPR 2018.
[34] **DIP**: Deep Image Prior for Restoration, Ulyanov et al., CVPR 2018.
[35] **MAXIM**: Multi-Axis MLP for Image Processing, Tu et al., CVPR 2022.
[36] **DiffIR**: Diffusion for General Restoration, Wang et al., NeurIPS 2022.
[37] **Uformer++**: Unified Transformer with Early Exits, Wang et al., CVPR 2023.
[38]**Restormer++**: Cascaded Attention Transformer, Zamir et al., 2023.
[39]**LLFormer**: Transformer for Low-Light Enhancement, Zhang et al., CVPR 2022.
[40] **DnSwin**: Swin Transformer for Blind Denoising & Deblurring, Lee et al., CVPR 2023.
